

# A Markov chain for lattice polytopes

Julien David, Lionel Pournin, Rado Rakotonarivo

February 20, 2018

**Abstract.** This paper describes an approach to the random sampling of lattice polytopes. The lattice polytopes we are interested in are contained in the hypercube  $[0, k]^d$  and we refer to them as lattice  $(d, k)$ -polytopes. Our approach consists in using a Markov chain whose space of states is the set of all  $d$ -dimensional lattice  $(d, k)$ -polytopes and whose transitions add or delete vertices following simple, well-defined rules. We prove that this Markov chain provides a uniform random sampler of lattice  $(d, k)$ -polytopes. We also give an upper bound for the mixing time when  $d = 2$  and present a number of experimental results on the mixing time for a selection of values for  $k$  and  $d$ .

## 1 Introduction

A polytope is the convex hull of a finite set of points in  $\mathbb{R}^d$ . These objects appear in a wide range of mathematical works, both in theoretical and applied contexts [2], yet their combinatorics is not well understood. A class of polytopes of special interest in combinatorics is that of *lattice  $(d, k)$ -polytopes*. These polytopes are contained in the hypercube  $[0, k]^d$ , where  $k$  is a positive integer, and their vertices have integer coordinates. In order to better understand this class of polytopes, we design a random sampler for them using a Markov chain whose space of states is the set of all  $d$ -dimensional lattice  $(d, k)$ -polytopes.

The transitions in this Markov chain, and the resulting random sampler can be described informally as follows. Given a lattice  $(d, k)$ -polytope  $P$  with vertex set  $\mathcal{V}$ , performing a transition will first consist in randomly choosing a lattice point  $x$  in  $[0, k]^d$ , and then to proceed according to the placement of  $x$  with respect to  $P$ . If  $x$  belongs to  $\mathcal{V}$ , then  $P$  will be replaced by the convex hull of  $\mathcal{V} \setminus \{x\}$ , thus removing  $x$  from  $P$ . If  $x$  does not belong to  $\mathcal{V}$  and  $\mathcal{V} \cup \{x\}$  is precisely the vertex set of its convex hull, then  $P$  will be replaced by the convex hull of  $\mathcal{V} \cup \{x\}$ , thus inserting  $x$  in  $P$ . If none of these two cases occurs, then  $P$  will not be affected. A formal definition of this Markov chain shall be given in Section 2. In this article we provide both theoretical and experimental results regarding the behaviour of this Markov chain. Our main result is that the resulting random sampler for lattice  $(d, k)$ -polytopes is uniform. This is shown in Section 3. Section X concludes the article with a number of experiments on the mixing time of our Markov chain.

Figure 1: An illustration of the transition rule for a triangle (depicted in grey), depending on the placement of point  $x$ , colored red when the chain loops and blue when it does not loop: (1)  $x$  belongs to  $P \setminus \mathcal{V}$ , (2) the convex hull of  $\mathcal{V} \cup \{x\}$  is  $(d-1)$ -dimensional, (3)  $\mathcal{V} \cup \{x\}$  is not the vertex set of its convex hull, and (4) the transition changes  $P$  into the convex hull of  $\mathcal{V} \cup \{x\}$ .

## 2 The Markov chain

We will consider a Markov chain whose space of states  $\Omega$  is the set of all  $d$ -dimensional lattice  $(d, k)$ -polytopes, for fixed  $d$  and  $k$ . A priori, the definition of lattice  $(d, k)$ -polytopes does not requires them to be  $d$ -dimensional. Some effort will be needed in order to enforce the requirement that all the states of our Markov chain are polytopes of dimension exactly  $d$ . The transition rules of our Markov chain are defined as local operations on lattice  $(d, k)$ -polytopes. These rules consist in adding or removing a given vertex to such a polytope. Consider a  $d$ -dimensional lattice  $(d, k)$ -polytope  $P$  and denote by  $\mathcal{V}$  its vertex set. Consider a lattice point  $x$  in  $[0, k]^d$  which, we assume has been uniformly drawn from all possible lattice points in  $[0, k]^d$ . The transition from  $P$  that corresponds to the chosen lattice point  $x$  goes as follows.

- If  $x$  is contained in  $P$  but is not a vertex of it (i.e.  $x \in P \setminus \mathcal{V}$ ) then the chain will loop on  $P$ . In other words, the current state is unaffected.
- If  $x$  is a vertex of  $P$  (i.e.  $x \in \mathcal{V}$ ), then
  - If the convex hull  $Q$  of  $\mathcal{V} \cup \{x\}$  is  $d$ -dimensional, the transition goes from  $P$  to  $Q$ . Note that if  $Q$  were  $(d-1)$ -dimensional, then  $P$  would be a pyramid (with apex  $x$ ) over  $Q$ . In this case, the transition from  $P$  to  $Q$  would be impossible because it would exit  $\Omega$ .
  - Otherwise, we loop on  $P$ .
- If  $x$  does not belong to  $P$ , then
  - If  $\mathcal{V} \cup \{x\}$  is precisely the vertex set of its convex hull, then the transition goes from  $P$  to the convex hull of  $\mathcal{V} \cup \{x\}$ .
  - Otherwise we loop on  $P$ .

Figure 1 illustrates transition rule in the case of a lattice triangle  $P$  contained in the square  $[0, 4]^2$ , depending on the placement of point  $x$ . Note that in this particular case, there is no transition that deletes a vertex of  $P$ .

### 63 3 Properties of the Markov chain

64 The purpose of this section

65 The purpose of this paper is to build the random sampler of  $(d, k)$ -polytopes,  
 66 in order to achieve our goal, we need to ensure that the stationnary distribution  
 67 on  $\Omega$  is the uniform. An important result on Markov chains shows that an irre-  
 68 ducible, aperiodic and symmetric Markov chain admits as stationnary distribution  
 69 the uniform [1].

70 This section aim to verify these properties on  $(X_t)$ , and give our first results  
 71 on  $(X_t)$ . Only verifying the irreducibility has been slightly tricky, the other ones  
 72 can be directly proved. In order to do so, the notion of symmetric difference on  
 73 our states will be introduced. Thereby, given  $x$  and  $y \in \Omega$ , we recall that their  
 74 *symetric difference*,  $x \triangle y$ , is defined as:

$$x \triangle y = x \cup y \setminus x \cap y \quad (1)$$

75 Recall that the irreducibility mean that all the states of  $\Omega$  can be reached  
 76 from any other state, thus the irreducibility guarantees that the graph with  
 77 vertex set  $\Omega$  is connected. In fact move from  $x$  to  $y$  in our chain consists in  
 78 finding finite number of transitions between  $x$  and  $y$  by one. Observe that the  
 79 simplest way to move from  $x$  to  $y$  consists in adding directly to  $x$  the vertices of  
 80  $y$  then remove  $x$  vertices. This means that at each step one reduces the symmetric  
 81 difference between  $x$  and  $y$ . Hence, one can verify that the cardinality of  $x \triangle y$   
 82 is a lower bound for the distance, noted  $\delta(x, y)$ , between  $x$  and  $y$ . One has:

$$\delta(x, y) \geq |x \triangle y| \quad (2)$$

83 However, we might face cases which not allow this fast transition, thus we  
 84 have to find out other transition state instead of those *trivial* cases. Let us take  
 85 into account the difficult cases and introduce lemmas to build our proof to the  
 86 irreducibility. Not being able to add a point  $w \in y \setminus x$  to  $x$  means that for all  
 87  $w \in y \setminus x$  the following cases occur:  $w$  is an interior point to  $x$ ,  $w$  belongs to  
 88 the affine hull of the edge of  $x$ ,  $w$  belongs to the cone described by one vertex of  
 89  $x$  and the two edges which contains this vertex. To overcome this problem, we  
 90 claim that we can always find a point  $v$  in  $[0, k]^d$  we can add to  $x$ , have a new  
 91 state from wich we are building the path to  $y$ , then ensure the irreducibility.

#### 92 3.1 Existence of $v$

93 Consider a  $d$ -dimensional lattice  $(d, k)$ -polytope  $\mathcal{S}$  and assume that  $\mathcal{S}$  is a sim-  
 94 plex. Let  $\mathcal{V}$  be the set of vertices of  $\mathcal{S}$ . For any  $u \in \mathcal{V}$ , denote by  $H_u$  the affine  
 95 hull of the facet of  $\mathcal{S}$  opposite  $u$ , and by  $H_u^-$  the closed half-space of  $\mathbb{R}^d$  limited  
 96 by  $H_u$  that does not contain  $u$ . For any  $v \in \mathcal{V}$ , the set

$$C_v = \bigcap_{u \in \mathcal{V} \setminus \{v\}} H_u^- \quad (3)$$

97 is a  $d$ -dimensional cone pointed at  $v$ . This cone is exactly the set of the  
 98 points  $x \in \mathbb{R}^d$  such that the convex hull of  $\mathcal{S} \cup \{x\}$  does not admit  $v$  as a vertex.  
 99 By this remark, we have the following lemma.

100 **Lemma 3.1.1.** *Let  $x$  be a lattice point in  $[0, k]^d$ . The convex hull of  $\mathcal{S} \cup \{x\}$*   
 101 *admits, as vertices,  $x$  and all the vertices of  $\mathcal{S}$  if and only if  $x$  does not belong*  
 102 *to  $\mathcal{S}$  and, for all  $v \in \mathcal{V}$ ,  $x$  does not belong to  $C_v$ .*

Call  $\gamma = \min\{x_1 : x \in \mathcal{S}\}$ . Consider the following hyperplane of  $\mathbb{R}^d$ :

$$X = \{x \in \mathbb{R}^d : x_1 = \gamma\}$$

103 Denote by  $X^-$  the open half-space of  $\mathbb{R}^d$  bounded by  $X$  and that does not  
 104 contain  $\mathcal{S}$ . By construction, the intersection  $\mathcal{S} \cap X$  is a non-empty, proper face  
 105 of  $\mathcal{S}$ . This face will be denoted by  $F$  in the following. Since  $\mathcal{S}$  is a simplex, it  
 106 admits another, non-empty face  $F^*$  whose vertices are exactly the vertices of  $\mathcal{S}$   
 107 that do not belong to  $F$ .

By construction,

$$\dim(F) + \dim(F^*) = d - 1.$$

108 In particular, there exists a vector  $c$  that is orthogonal to both  $F$  and  $F^*$ .  
 109 Consider the hyperplane  $Y$  of  $\mathbb{R}^d$  that admits  $c$  as a normal vector and such  
 110 that  $F^* \subset Y$ . The intersection  $\mathcal{S} \cap Y$  is precisely  $F^*$ . Denote by  $Y^-$  the closed  
 111 half-space of  $\mathbb{R}^d$  bounded by  $Y$  that does not contain  $F$ . It will be assumed  
 112 that  $c$  has norm 1 and that it points towards  $Y^-$ . Let

$$\delta = \min\{c \cdot x : x \in X \cap [0, k]^d\}. \quad (4)$$

113 Further denote  $G = \{x \in X \cap [0, k]^d : c \cdot x = \delta\}$ . In the statement of the  
 114 following lemma,  $\text{aff}(F)$  denotes the affine hull of  $F$ .

**Lemma 3.1.2.** *If  $v$  is a vertex of  $\mathcal{S}$ , then*

$$C_v \subset \text{aff}(F) \cup X^- \cup Y^-.$$

*Proof.* First observe that, if  $s$  is a face of  $\mathcal{S}$  and  $H$  is a hyperplane of  $\mathbb{R}^d$  that intersects  $\mathcal{S}$  exactly along  $s$ , then

$$\bigcap_{u \in \mathcal{V} \setminus s} H_u^- \subset H^-,$$

where  $H^-$  is the closed half space of  $\mathbb{R}^d$  bounded by  $H$  and disjoint from the interior of  $\mathcal{S}$ . Further observe that the intersection of  $H$  with

$$\bigcap_{u \in \mathcal{V} \setminus s} H_u^-$$

115 is precisely the affine hull of  $\mathcal{S}$ . As a direct consequence, taking in turn  $s = F^*$   
 116 and  $s = F$ , one obtains that, if  $v$  is a vertex of  $F$ , then  $C_v \subset \text{aff}(F) \cup X^-$  and  
 117 if  $v$  is a vertex of  $F^*$ , then  $C_v \subset Y^-$ . The result therefore holds because any  
 118 vertex of  $\mathcal{S}$  is either a vertex of  $F$  or a vertex of  $F^*$ . ■

119 As an immediate consequence of this and Lemma 3.1.1, for any lattice point  
 120  $x \in [0, k]^d$  that does not belong to  $X^-$ , to  $Y^-$ , or to the affine hull of  $F$ , the  
 121 convex hull of  $\mathcal{S} \cup \{x\}$  admits, as vertices,  $x$  and all the vertices of  $\mathcal{S}$ .

122 Recall that  $c$  is orthogonal to  $F$  and  $F^*$ . As a consequence, the map  $x \mapsto c \cdot x$   
 123 is constant within  $F$  and within  $F^*$ . Call  $\varepsilon$  the value of  $c \cdot x$  when  $x \in F$  and  $\varepsilon^*$   
 124 the value of  $c \cdot x$  when  $x \in F^*$ . Since  $F$  and  $Y^-$  are disjoint,  $\varepsilon < \varepsilon^*$ . Moreover,  
 125 by (4),  $\delta \leq \varepsilon$ . Observe that if the latter inequality is strict, then  $G$  is disjoint  
 126 from both  $\text{aff}(F)$  and  $Y^-$ . By definition, it is also disjoint from  $X^-$  and the  
 127 following lemma is then obtained as a consequence of Lemmas 3.1.1 and 3.1.2.

128 **Lemma 3.1.3.** *If  $\delta < \varepsilon$ , then for any lattice point  $x \in G$ , the convex hull of*  
 129  *$\mathcal{S} \cup \{x\}$  admits, as vertices,  $x$  and all the vertices of  $\mathcal{S}$ .*

130 If, on the contrary,  $\delta$  and  $\varepsilon$  coincide, then  $F \subset G$ . This situation is familiar:  
 131 we are looking at a lattice simplex  $F$  contained in a (possibly degenerate) lattice  
 132 cube  $G$ . If the dimension of  $G$  is greater than the dimension of  $F$ , then the  
 133 following lemma provides the desired result.

134 **Lemma 3.1.4.** *If  $k$  and  $d$  are positive and if  $P$  is a lattice  $(d, k)$ -polytope of*  
 135 *dimension less than  $d$  then there exists a lattice point  $x$  that belongs to  $[0, k]^d$*   
 136 *but that does not belong to the affine hull of  $P$ .*

137 *Proof.* If  $P$  is a lattice  $(d, k)$ -polytope of dimension less than  $d$ , then the inter-  
 138 section  $I$  of its affine hull with  $[0, k]^d$  cannot contain more than  $(k+1)^{d-1}$  lattice  
 139 points. Indeed, one can always project  $I$  orthogonally on a facet of  $[0, k]^d$  in  
 140 such a way that the dimension of the projection is not less than that of  $I$ . Such  
 141 a projection induces an injection from the lattice points in  $I$  into the lattice  
 142 points in the facet on which the projection is made.

143 Now observe that  $[0, k]^d$  contains  $(k+1)^d$  lattice points. Since  $k$  is positive,  
 144  $(k+1)^{d-1} < (k+1)^d$  and the lemma is proven. ■

145 Hence, it remains to solve the case when  $F$  is a subset of  $G$  and both have  
 146 the same dimension. If this dimension is at least 2, then the strategy is to argue  
 147 by induction on  $d$ . The base case of the induction is given by the following  
 148 lemma.

149 **Lemma 3.1.5.** *If  $d = 2$  then there exists a lattice point  $x \in [0, k]^2$  such that*  
 150 *the convex hull of  $\mathcal{S} \cup \{x\}$  admits, as vertices,  $x$  and all the vertices of  $\mathcal{S}$ .*

151 *Proof.* Probably just a careful, hopefully short disjunction. Rado, Julien? ■

152 The case when  $F$  is a subset of  $G$  and their common dimension is either 0  
 153 or 1 has to be treated separately.

154 **Lemma 3.1.6.** *Assume that  $d$  is greater than 2. If  $G$  has dimension at most 1*  
 155 *and admits  $F$  as a subset, then there exists at least one lattice point  $x$  in  $[0, k]^d$*   
 156 *that does not belong to  $\text{aff}(F) \cup X^- \cup Y^-$ .*

157 *Proof.* Assume that the dimension of  $G$  is 0 or 1 and that  $F$  is a subset of  
 158  $G$ . Because of the latter assumption,  $\delta = \varepsilon$ . Further assume that every lattice  
 159 point in  $X \cap [0, k]^d$  belongs to either  $\text{aff}(F)$  or  $Y^-$ . Since  $Y^-$  is the set of points  
 160  $x \in \mathbb{R}^d$  such that  $c \cdot x \geq \varepsilon^*$ , this assumption yields that any lattice point  $x$  in  
 161  $X \cap [0, k]^d$  such that  $c \cdot x < \varepsilon^*$  satisfies  $c \cdot x = \delta$ .

162 In particular, the only lattice points in  $X \cap [0, k]^d$  that may belong to  $Y$  have  
 163 distance exactly 1 to some lattice point in  $G$ .

164 Now consider the set  $N$  of the points  $x$  in  $[0, k]^d$  whose orthogonal projection  
 165 on  $X$  belongs to  $G$  and such that  $x_i = \gamma + 1$ . By construction,  $\gamma < k$  and  
 166 therefore,  $N$  is non-empty. More precisely,  $N$  is made up of a single point if  
 167  $G$  has dimension 0, and  $N$  is a line segment parallel to  $G$  if  $G$  has dimension  
 168 1. In particular, the map  $x \mapsto c \cdot x$  is constant within  $N$ . Call this constant  $\eta$ .  
 169 If  $\eta \geq \varepsilon^*$ , then the only lattice points  $x$  in  $[0, k]^d$  such that  $x_i \geq \gamma$  that may  
 170 belong to  $Y$  are the ones whose distance to some lattice point in  $G$  is exactly  
 171 1. Among these candidates, the only ones that can also be vertices of  $\mathcal{S}$  are

the lattice point in  $N$ . Indeed, all the other candidates belong to  $X$ . This is impossible because  $\mathcal{S}$  would then be contained in the convex hull of  $G \cup N$  whose dimension is either 1 or 2 depending on the dimension of  $G$ , whereas the dimension of  $\mathcal{S}$  is at least 3.

It follows from this contradiction that  $\eta < \varepsilon^*$ . In other words,  $N$  is disjoint from  $Y^-$ . By construction,  $N$  is also disjoint from  $X^-$  and from the affine hull of  $F$ . As  $N$  contains lattice points, this proves the lemma. ■

Here now comes the following proposition we want to claim.

**Proposition 3.1.1.** *There exists a lattice point  $x$  in the cube  $[0, k]^d$  such that the convex hull of  $\mathcal{S} \cup \{x\}$  admits, as vertices,  $x$  and all the vertices of  $\mathcal{S}$ .*

*Proof.* We need to write the induction carefully. Rado, Julien? ■

### 3.2 Irreducibility of $(X_t)$

**Lemma 3.2.1.** *For any simplex  $x \in \Omega$ , for any  $y \in \Omega$ . If we cannot reduce  $x \triangle y$  by adding a vertex in  $y \setminus x$  there exists a simplex  $z \in \Omega$ , a transition state between  $x$  and  $y$ , which verifies:*

- $|x \triangle y| = |z \triangle y|$
- $\delta(x, z) \leq 2$

such that we can always add a vertex in  $y \setminus z$ , from  $z$  to  $y$ .

*Proof.* Let be  $x$  a simplex  $y$  be in  $\Omega$ . Let be  $v \in [0, k]^d$ . The idea of the proof lies on the fact that,  $z$  will be found by adding a point  $v \in \Omega$  and which is not an element of  $x \triangle y$ , then remove a point of  $x \setminus y$ . In this way we found the simplex  $z$  at most in 2 steps. ■

**Lemma 3.2.2.** *For all  $x$  and  $y \in \Omega$ , there exists  $z \in \Omega$  which satisfies  $|x \triangle y| > |z \triangle y|$  such that  $\delta(x, z) \leq 3$ .*

*Proof.* Let  $x$  and  $y$  be states of  $\Omega$ , such that  $P(x, y) = 0$ . Let  $z$  be a transition state between  $x$  and  $y$ , and such that  $z$  is closer to  $y$  than  $y$ . We have several distinct cases:

1.  $x$  is not a simplex.

- (a)  $x \subset y$ : add  $v \in y \setminus x$  and  $z = x \cup \{v\}$ , then  $\delta(x, z) = 1$
- (b)  $x \not\subset y$ : remove  $v \in x \setminus y$  and  $z = x - \{v\}$ , then  $\delta(x, z) = 1$

2.  $x$  is a simplex.

- (a) If we can add  $v \in y \setminus x$  then add it, thus  $z = x \cup \{v\}$  and  $\delta(x, z) = 1$
- (b) Else:

- i. Add a point  $u$  which is not in  $x \triangle y$
  - ii. Remove a point from  $x \setminus y$
  - iii. Add a point from  $y \setminus x$
- In this last case, one finds  $z$  such that  $\delta(x, z) = 3$

209 Since we had proved we can always add a point which is not contained in  
 210  $x \triangle y$  by lemma 3.2.1. It means that wherever in which case we are, one can  
 211 always find a  $z$  which reduces the symetric difference from  $z$  to  $y$  by one, such  
 212 that  $\delta(x, z) \leq 3$ .  
 213 ■

214 **Corollary 3.2.1.** *For all  $x$  and  $y \in \Omega$  one has:*

$$\delta(x, y) \leq |x| + |y| + 4(d + 1) \quad (5)$$

*Proof.* This is an immediate consequence of the lemma 3.2.2. Let  $x$  and  $y$  be in  $\Omega$ . Let us now consider two simplices  $x^*$  and  $y^*$  such that  $\delta(x, x^*) = |x| - (d + 1)$ , and  $\delta(y, y^*) = |y| - (d + 1)$ . Thus

$$\delta(x, y) \leq \delta(x, x^*) + \delta(x^*, y^*) + \delta(y, y^*)$$

Since  $x^*$  is a simplex, the walk needs at most  $3(|x^*| + |y^*|) = 3 \times 2(d + 1)$  steps to reach  $y^*$  from  $x^*$ . Hence

$$\delta(x, y) \leq |x| - (d + 1) + |y| - (d + 1) + 6(d + 1) = |x| + |y| + 4(d + 1)$$

215 ■

216 Observe that corollary 3.2.1 gives an idea on the upper bound of the diameter  
 217 of  $(X_t)$ . We have now settled all we need to prove our main results on the  
 218 properties of  $(X_t)$ .

219 **Theorem 1.** *Define the diameter  $\mathcal{D}$  of a graph with vertex set  $\Omega$  to be the*  
 220 *maximum distance between two vertices. For  $(X_t)$ , as defined above, and given*  
 221  *$k$  and  $d$ , one has:*

$$\mathcal{D}_{X_t} \leq 2ck^{3/4} + 4(d + 1) \quad \text{where } c > 0 \quad (6)$$

222 *Proof.* To be done. ■

223 **Theorem 2.** *The Markov chain  $(X_t)$  is irreducible, aperiodic and has the*  
 224 *uniform as stationnary distribution.*

225 *Proof.* Three propreties have to be verified, thus this proof will be given in three  
 226 steps. Let  $x$  and  $y$  be in  $\Omega$ .

- 227 i *Irreducibility* Irreducibility is a direct consequence of the corollary 3.2.1. Let  
 228 us remind that to prove the irreducibility, one needs to find a  $r_0$  such that,  
 229 for all  $x$  and  $y \in \Omega$ , when  $r \geq r_0$  then  $P^r(x, y) > 0$ . Thus let us take  
 230  $r_0 = |x| + |y| + 4(d + 1)$ .
- 231 ii *Symetry* Our transition rules consists in either add or remove a single vertex  
 232 for two distinct states. Observe that if there is no one step transition from  
 233  $x$  to  $y$  means  $P(x, y) = 0$ . By the trasition rules, necessarily, if  $P(x, y) = 0$   
 234 then  $P(y, x) = 0$ . Next, let us prove that if  $P(x, y) > 0$  and  $P(y, x) > 0$   
 235 then we also have  $P(x, y) = P(y, x)$ .  $P(x, y) > 0$  means that we have a one  
 236 step transition from  $x$  to  $y$ . Only two cases may occur. For  $v \in [0, k^d]$  either  
 237  $y = x - \{v\}$ , or  $y = x \cup \{v\}$ . Considering the first case, the probability  
 238 to draw  $v$  and add it to  $x$  is  $P(x, y) = \frac{1}{(k+1)^d}$ . Similarly, to move from  $y$   
 239 to  $x$ , we draw the same  $v$  and remove it from  $y$  to get  $x$  with probability  
 240  $P(y, x) = \frac{1}{(k+1)^d} = P(x, y)$ . We prove the remaining case in an analog  
 241 reasoning.

242 iii *Aperiodicity* To prove that  $(X_t)$  is aperiodic, one needs to show that each  
 243 state in  $\Omega$  has as period 1. Since  $(X_t)$  is irreducible, property ?? tells us that  
 244 all the states of  $\Omega$  has the same period. Thus, for all  $x, y \in \Omega$ ,  $\gcd(\mathcal{T}(x)) =$   
 245  $\gcd(\mathcal{T}(y))$ . One needs to find a state  $x$  such that  $\gcd(\mathcal{T}(x)) = 1$ . Let us  
 246 take  $x$  has a simplex and a point  $v \in [0, k]^d$  then consider the cases where we  
 247 have a loop on  $x$ : either  $v$  is an interior point to  $x$ , or  $v$  is drawn outside of  $x$   
 248 but  $|Conv(x \cup \{v\})| \neq |x| + 1$ . One has:  $P(x, x) = \mathbf{P}\{v \text{ interior point to } x\} +$   
 249  $\mathbf{P}\{v \in x\} + \mathbf{P}\{|x \cup \{v\}| \neq |x| + 1\}$ . Note that  $\mathbf{P}\{v \in x\} = \frac{1}{(k+1)^d}$ , but since  
 250  $|x| = d + 1$ , we have a loop on  $x$  with probability  $P(x, x) \geq \frac{1}{(k+1)^d} > 0$ . In  
 251 another words, with positive probability the walk can get back to  $x$  from  $x$   
 252 in one step. Hence,  $\mathcal{T}(x) = \{1, \dots\}$ . We conclude that  $\gcd(\mathcal{T}(x)) = 1$ .

## 254 4 Random sampler

255 Consider  $(X_t)$  as defined previously. Sampling random  $(d, k)$ -polytopes consists  
 256 in a random walk on  $\Omega$  with our transition rules until one reaches the stationary  
 257 distribution. The amount of time needed to reach such a distribution, that is  
 258 sample a uniformly random  $(d, k)$ -polytope, is the mixing time on  $(X_t)$ .

259 Sampling a random  $(d, k)$ -polytope with this model is given the following  
 260 algorithm.

---

**Algorithm 1:**  $\Gamma(d, k)$ : Sample a  $(d, k)$ -polytope

---

**Input:** the dimension  $d$ , the side  $k$  of the hypercube

**Output:** random  $(d, k)$ -polytope drawn in  $[0, k]^d$

---

```

1 arbitrary initial state  $x_0$ 
2 while the stationary distribution is not reached do
3   draw a random point  $v$  in  $[0, k]^d$ 
4   if  $v \in x_0$  et  $|x_0| > d + 1$  then
5      $x_0 = x_0 - \{v\}$ 
6   else if  $|Conv(x_0 \cup \{v\})| == |x_0| + 1$  then
7      $x_0 = x_0 \cup \{v\}$ 
8 return  $x_0$ 

```

---

262 **Theorem 3.** The random sampler  $\Gamma(d, k)$  described by algorithm 1 is a uniform  
 263 random sampler of  $(d, k)$ -polytopes over  $\Omega$ .
